Generate a concise graduate-level technical summary of this assignment on automated optimization of feature distributions using an AutoML-inspired Muller loop.

Context:
Using the CERT r4.2 dataset, we built a user-level classification model (insider vs non-insider). Random Forest

Submit Text

This work presents an automated optimization strategy for feature distributions within a user-level insider threat classification task using the CERT r4.2 dataset. A Random Forest classifier established a strong baseline, achieving an F1-score of approximately 0.9476. Feature importance analysis identified `logon_count` as the most influential predictor.

To explore its distributional impact, an AutoML-inspired Muller loop was implemented to iteratively optimize a multiplier, `m`, applied to this feature. The optimization process involved an initial manual scoping phase ($m \in [0.7, 1.6]$) to define the hyperparameter search space, followed by an iterative, exit-condition-driven AutoML loop. This rigorous approach consistently identified `m=1.0` as the optimal multiplier, indicating the feature's original distribution was well-suited. Subsequent analysis using confusion matrices and train-test metrics confirmed stable model generalization capabilities, demonstrating that this optimization strategy neither compromised performance nor introduced overfitting.
